COMPLETE SOFTWARE TESTING WORKFLOW

1. Understand the Application

Before testing, fully understand the app's features, user flow, and expected behavior.

• Read requirements or PRD
• Identify critical flows (login, payment, navigation)
• Know expected outputs for each action

2. Define Test Scenarios

Break the app into scenarios:

• Login flow
• Form submission
• Navigation

Each scenario should represent a real user action.

3. Perform Manual Testing

Start with manual testing:

• Test happy path
• Test edge cases (empty input, invalid data)
• Try random/spam actions

Goal: Break the system like a real user.

4. Edge Case Testing

Test unusual conditions:

• Very large inputs
• Special characters
• Rapid clicks

These often reveal hidden bugs.

5. Browser & Device Testing

Use Chrome DevTools:

• Simulate slow network (3G)
• Test offline mode
• Test different screen sizes

Goal: Ensure app works in real-world conditions.

6. API Testing
Test backend separately:
• Use Postman
• Modify request data
• Try unauthorized actions (e.g., user → admin)
Goal: Ensure backend validates everything.

7. Automation Testing
Use tools like Selenium (web) and Appium (mobile):
• Automate login
• Automate forms
• Automate navigation
Run tests on every deploy.

8. Regression Testing
After every change:
• Re-test old features
• Ensure nothing broke
Automation helps here.

9. Performance Testing
Check app under load:
• Multiple users
• Slow response
Tools: JMeter, k6

10. Error Monitoring
Check console & logs:
• Fix warnings
• Track errors
Small issues become big bugs later.

11. User Simulation
Act like a real user:
• Random clicks
• Fast navigation

• Unexpected behavior
Users are unpredictable.

12. Final Rule
“If you didn’t try to break your app, you didn’t test it.”
